Name: Kristine Mae B. Bataller

Role: Backend (Seller) and Documentation

As assigned on the server-side, my task is to develop a REST API for Artistryx's seller functionality. Following the Create, Read, and Update in the CRUD operations, the system logic I implemented includes registering and updating the shop, as well as viewing shop information. First, I created and inserted a table named "sellers" into the existing database, with the necessary attributes. Then I made sure that it is connected to the "users" table to ensure data integrity and proper ownership of each shop.

After the user successfully logs in, the client-side will present four choices, specifically Register Shop, View Shop, Update Shop, and Logout, which sends corresponding requests to the REST API to process. The register shop uses a POST request that accepts shopName as parameter and first validates the userId. The code also confirms whether the user already has a shop and whether the shop name does not yet exist in the database before accepting the registration and storing it in the database with a default status of "Pending". Furthermore, View Shop is a GET request that allows the users to see and retrieve the shop details linked to their account. The update shop, on the other hand, is a PUT request that checks if the new name is the same as the current one and checks if it is already taken by another user before proceeding to update the shop name. Aside from coding the server-side seller functionality, I am also in charge of writing the documentation report for our group.

However, there were few challenges I encountered in database setup. Since I was using the older MySQL version, importing artistryx_db.sql resulted in error and incompatible issues such as the unrecognized collation utf8mb4_0900_ai_ci. Also, there was confusion in creating the "sellers" table as at first I tried to query first the "sellers" table before the "users", which was wrong to do.

In solving these challenges, I changed the collation utf8mb4_0900_ai_ci to utf8mb4_general_ci, which is compatible with the older MySQL version in XAMPP. I resolved the second issue by manually running the SQL statements (phyMyAdmin SQL tab) in the correct order.
